Introduction – Heliostat Wind Loads

- Part-depth atmospheric boundary layer (ABL) in wind tunnel experiments limited in scaling both horizontal and vertical turbulence
- Dynamic loads based on streamwise wind speed and turbulence intensity can underestimate wind-induced displacements due to bending moments

Adapted from Emes *et al.* (2019), von Reeken *et al.* (2016), and Blume *et al.* (2020)

Emes *et al.* (2024), Journal
of Solar Energy Engineering

Wind tunnel experiments – instrumentation

- 1:114 part-depth ABL
 - Open farmland, grassy plains
- 1:6 scale heliostat model
 - $b = 0.33 \text{ m}$, $c = 0.53 \text{ m}$, $H = 0.25 \text{ m}$
- JR3 six-axis load cell
 - $\pm 100 \text{ N } F_x, F_y, \pm 200 \text{ N } F_z, \pm 12 \text{ Nm } M_x, M_y, M_z$ with $\pm 0.25\%$ accuracy
- 24 differential pressure sensors
 - $\pm 1'' \text{ H}_2\text{O}$ ($\pm 248.84 \text{ Pa}$) with $\pm 0.25\%$ accuracy

Wind tunnel experiments – ABL profiles

- Mean velocity profile

$$U(z) = \frac{u_\tau}{k} \ln \frac{z}{z_0} + d$$

$u_\tau = 0.48 \text{ m/s}$, $z_0 = 0.01 \text{ m}$, $d = 4.4$

$$U(z) = U_\infty \left(\frac{z}{\delta} \right)^\alpha$$

$U_\infty = 11.8 \text{ m/s}$, $\delta = 1.3 \text{ m}$, $\alpha = 0.35$

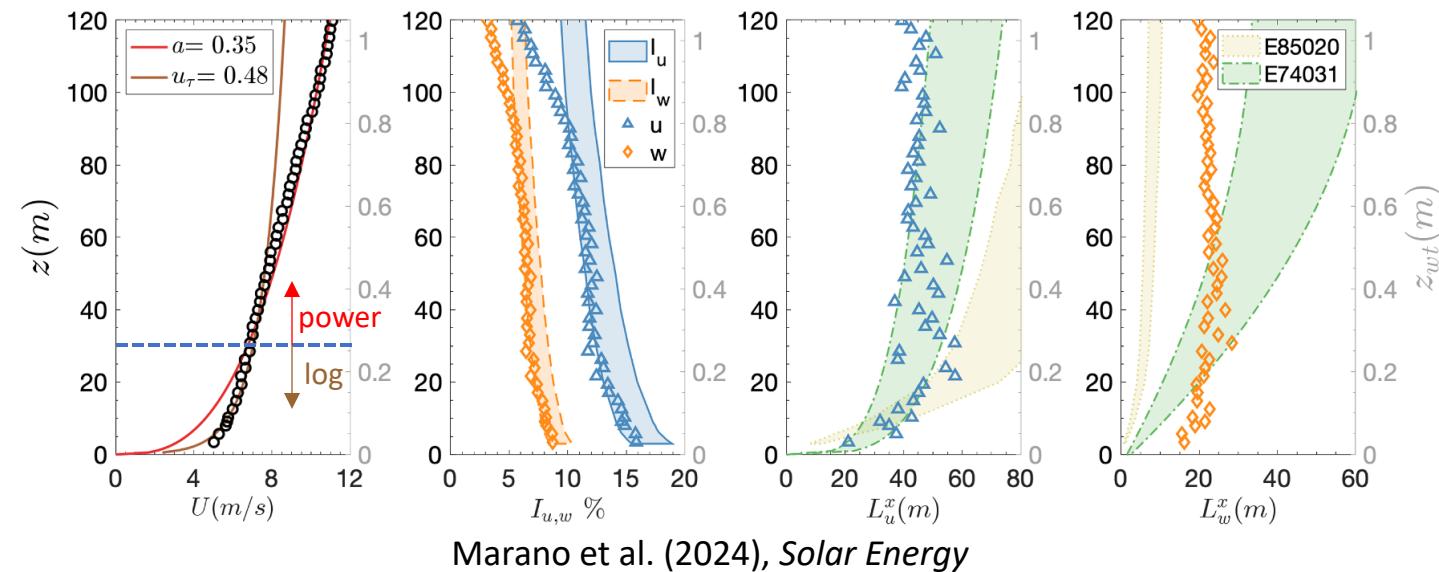

- Turbulence intensity profiles

$z_0 = 0.01 \text{ m}$ (ESDU 85020)

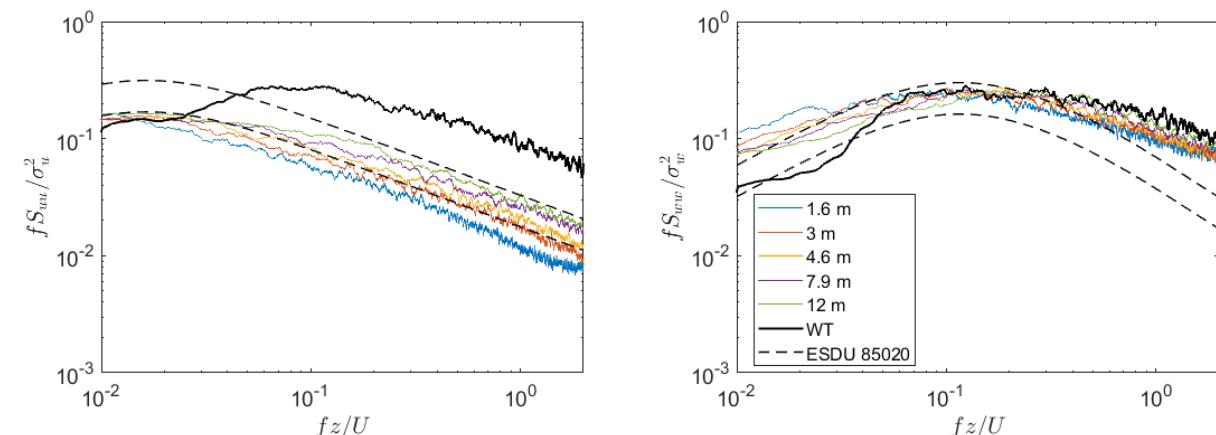

- Turbulence length scales

$z_0 = 0.01 \text{ m}$ (ESDU 85020)

$\alpha = 0.35$ (ESDU 74031)

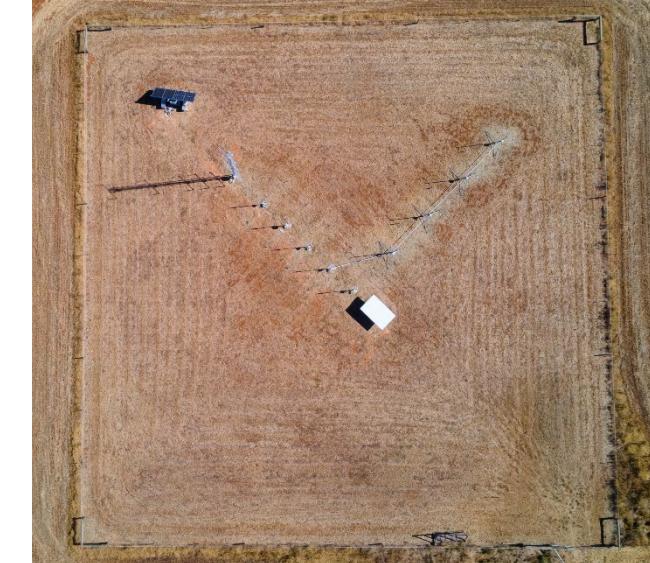

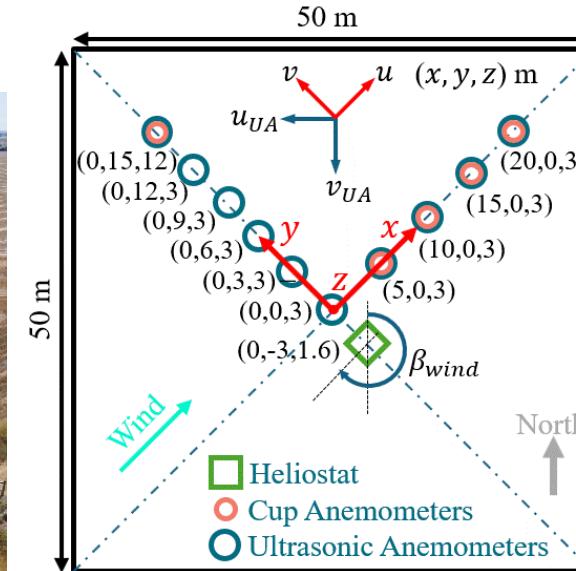

Marano et al. (2024), Solar Energy

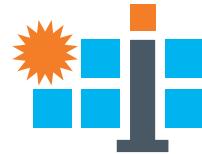

Emes et al. (2024), Solar Energy (under review)

ABLRF – layout

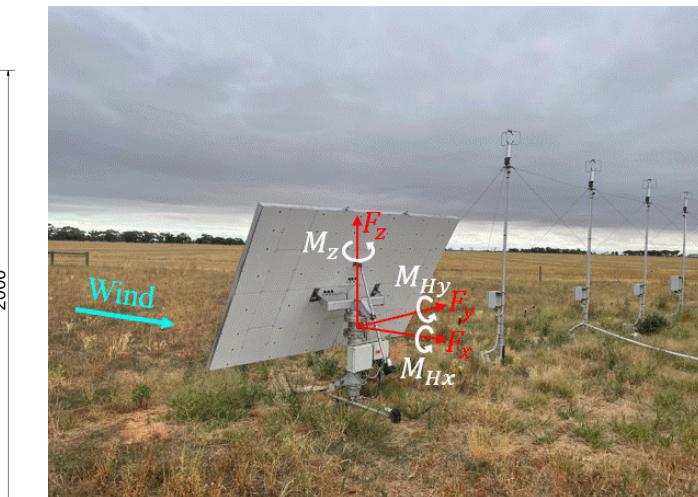

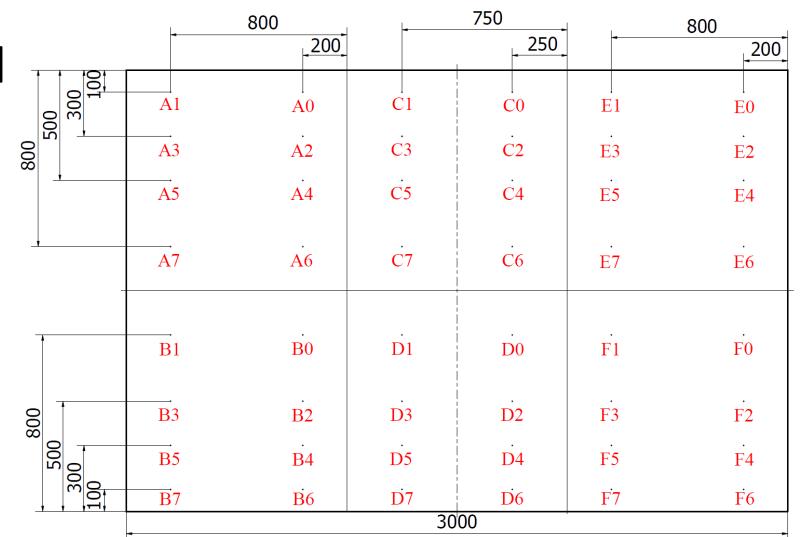

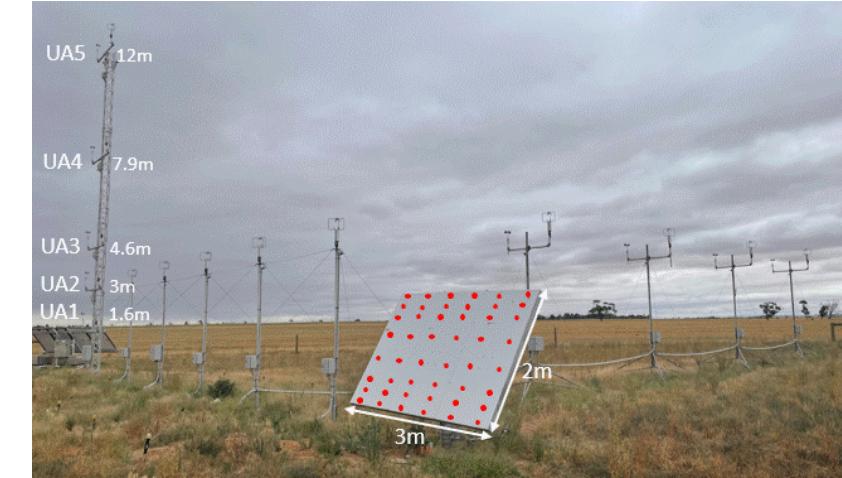

- 14 ultrasonic anemometers
- 9 cup anemometers
- Open farmland

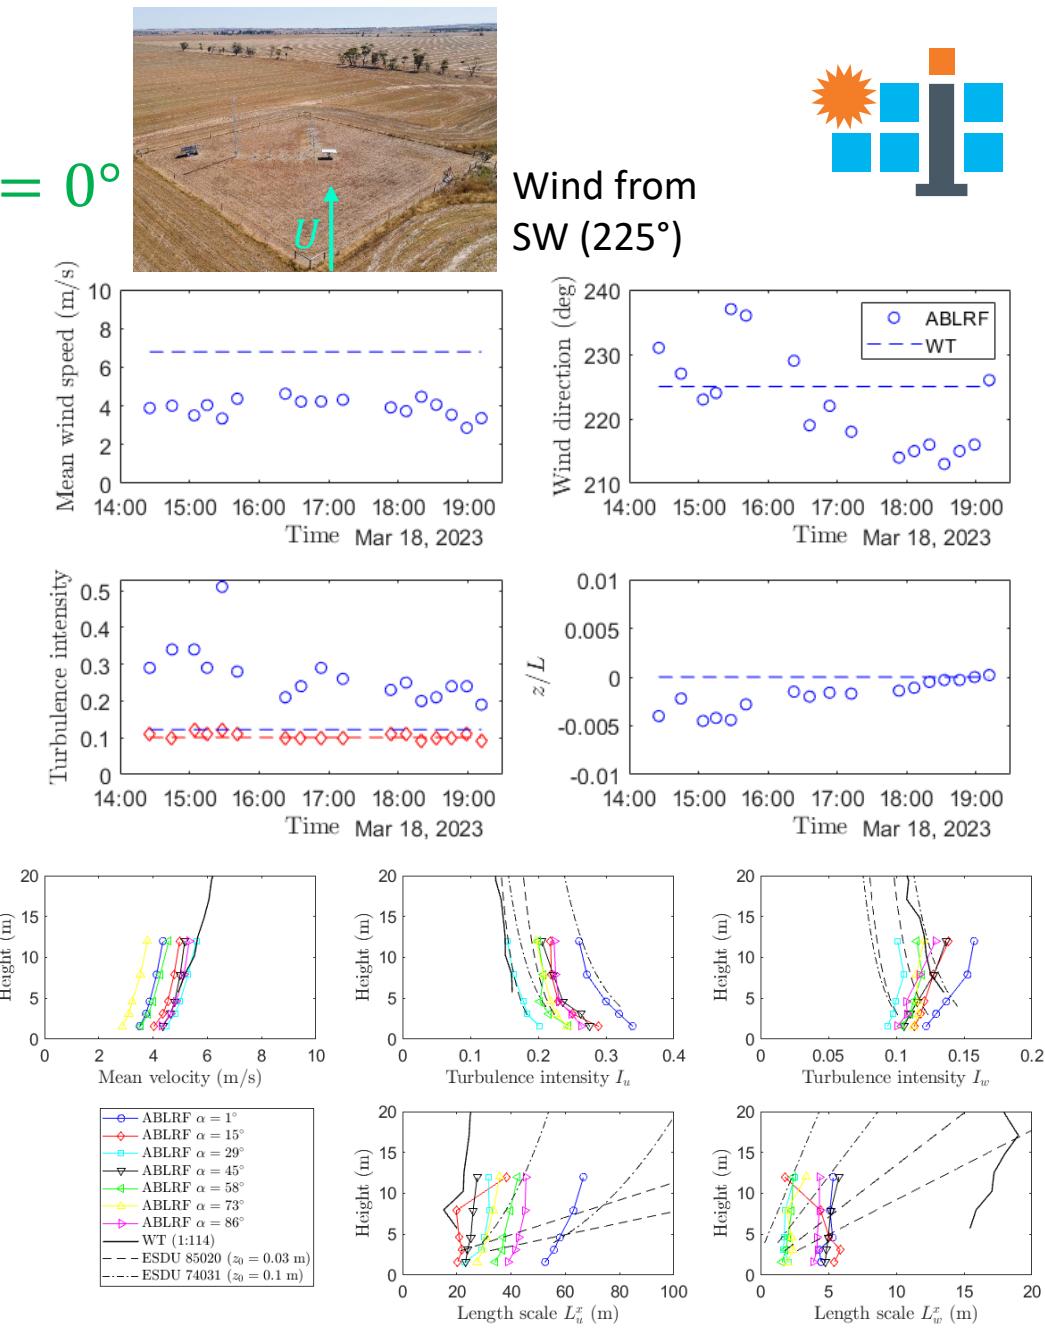

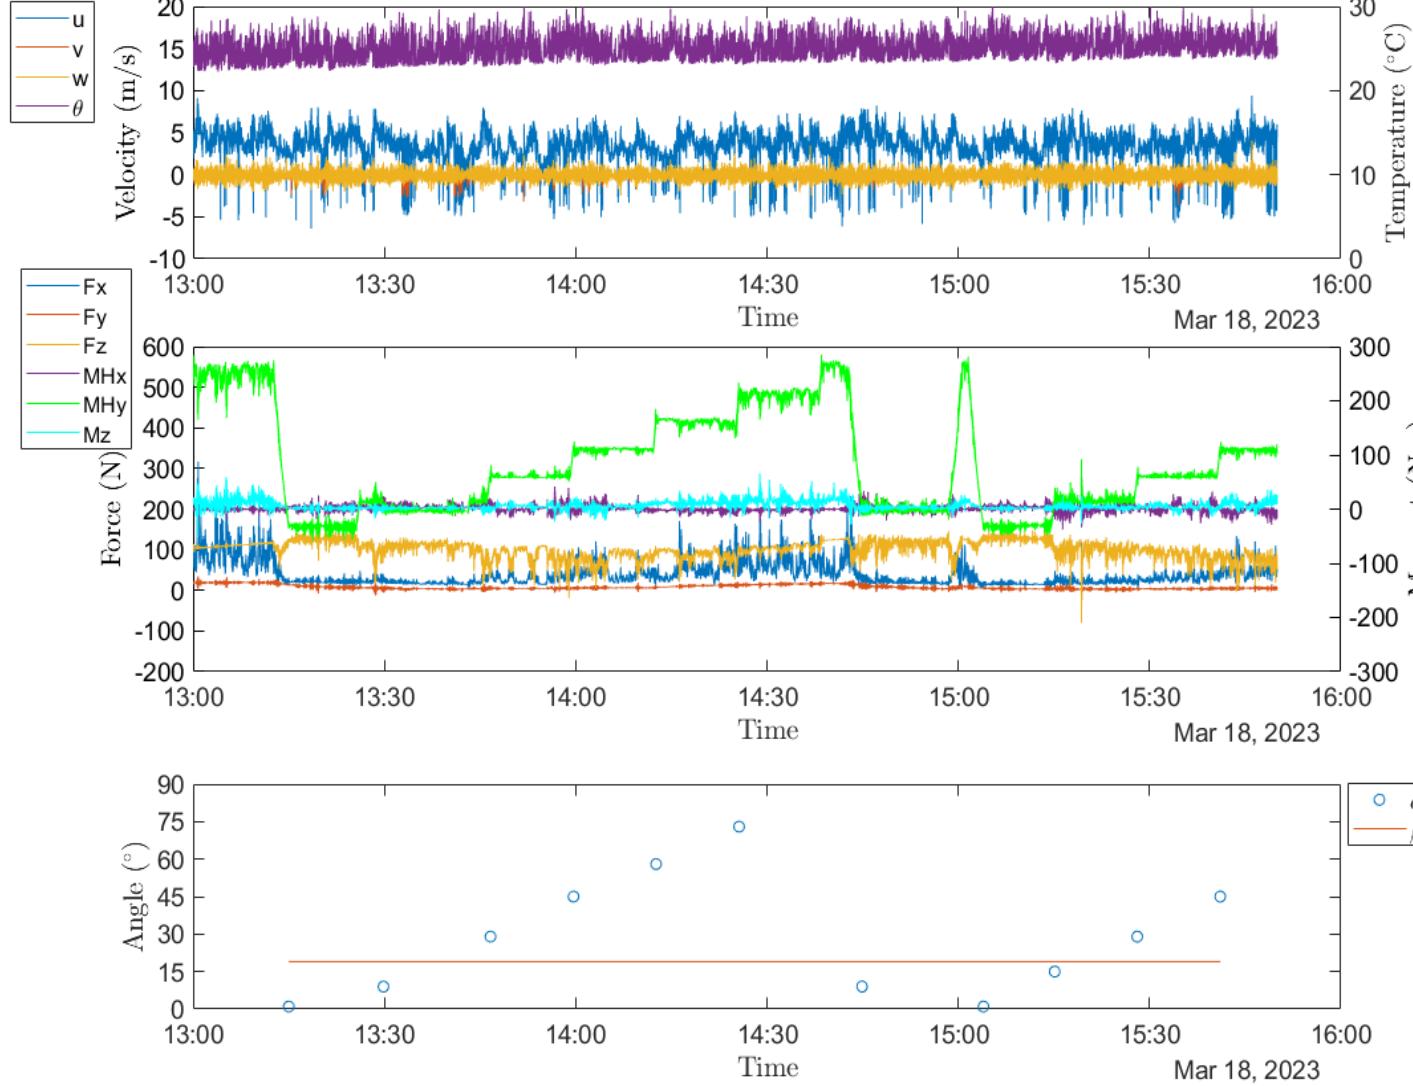

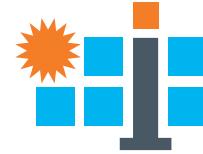

ABLRF – instrumentation

- Campbell Scientific 81005A 3D ultrasonic anemometers
 - ± 0.05 m/s accuracy
 - 0.01 m/s resolution
 - ± 2°C accuracy
 - 0.01°C resolution
- Risø P2546A cup anemometers
- 48 Honeywell HSC series differential pressure sensors
 - ±0.25% accuracy
 - ±600 Pa measurement range
- ME Systeme K6D175 six-axis load cell
 - ± 0.5% accuracy
 - ± 10 kN F_x , F_y , ± 20 kN F_z
 - ± 1 kNm M_{Hx} , M_{Hy} , ± 2 kNm M_z
- Single industrial computer, 4G modem, four 315 W photovoltaic panels and six 200 Ah batteries

Heliostat Wind Load Analysis

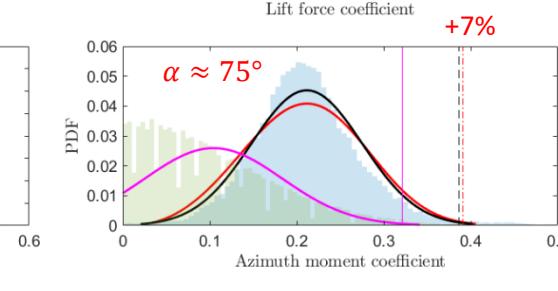

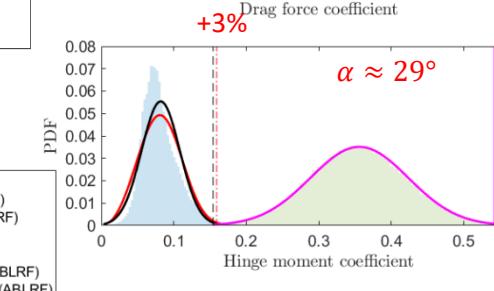

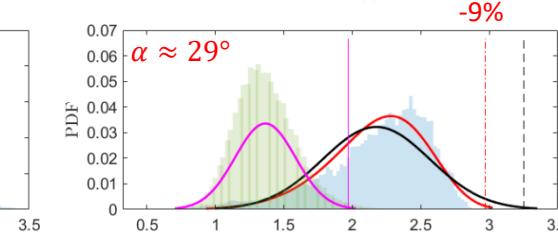

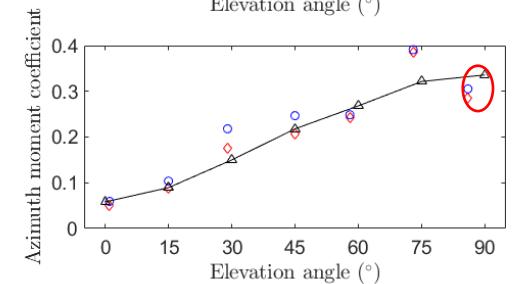

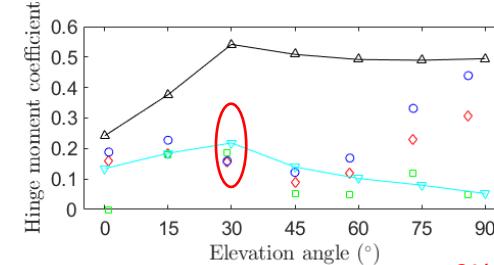

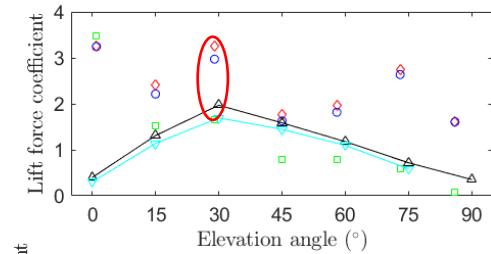

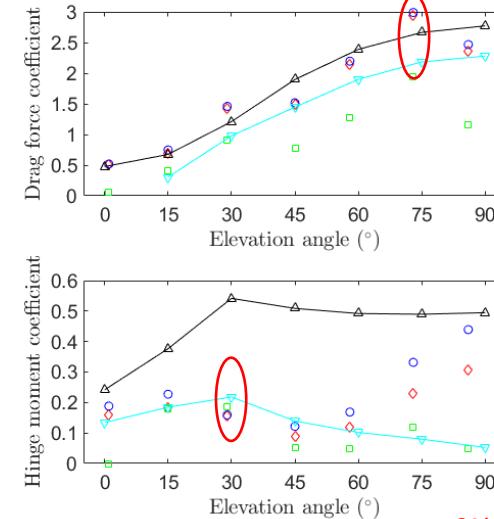

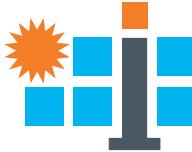

- Drag force and azimuth moment coefficients from load cell (LC) are consistent
- Lift force and hinge moment coefficients from pressure sensors (PS) are consistent but more than 50% difference from LC at $\alpha \leq 30^\circ$
- Influence of L_w^x/c greater than I_u and I_w
- Peak loads sufficiently estimated by a fitted Gaussian distribution

$\beta = 0^\circ$

- ◊ $\beta = 0^\circ$ ABLRF LC Gaussian
- $\beta = 0^\circ$ ABLRF LC Weibull
- $\beta = 0^\circ$ ABLRF PS Gaussian
- △ $\beta = 0^\circ$ WT LC Gaussian
- ▽ $\beta = 0^\circ$ WT PS Gaussian

Heliostat Wind Load Analysis

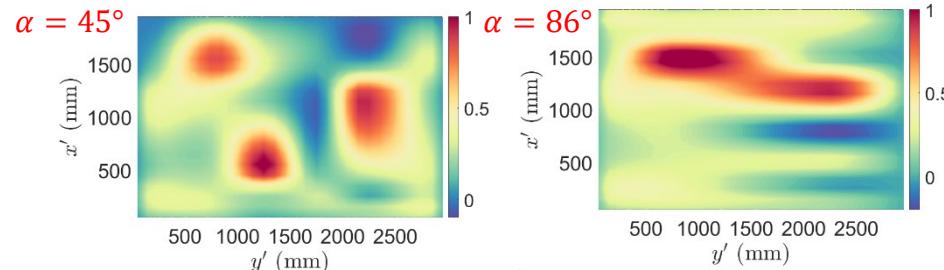

- Drag forces and azimuth moments overestimated in wind tunnel (WT) due to smaller $L_u^x/c \approx 1.3$ (10-15 ABLRF) and despite smaller I_u 12% (26-36% ABLRF)
- Lift forces underestimated in wind tunnel (WT) due to smaller $L_w^x/c \approx 0.53$ (0.4-1.3 ABLRF) and smaller I_w 11% (12-16% ABLRF)

Key Takeaways

- Single heliostat wind loads are sensitive to ABL turbulence intensity and integral length scales at elevation axis height
 - Drag forces at $\alpha \geq 60^\circ$ overestimated in wind tunnel experiments ($L_u^x/c \approx 1$) compared to field measurements ($L_u^x/c \approx 10$)
 - Lift forces at $\alpha \leq 30^\circ$ underestimated in wind tunnel experiments ($L_w^x/c \approx 0.5$) compared to field measurements ($L_w^x/c \approx 1$)
 - Wind loads that are more sensitive to the vertical component of velocity fluctuations (i.e. lift forces and hinge moments) show a greater dependence on atmospheric instabilities, such as amplified energy of turbulence in the vertical direction during the late afternoon and evening transition
 - Azimuth moments at different β show general agreement between wind tunnel and field measurements
 - All load coefficients at ABLRF show a small to negligible variation with changes in wind speed at heliostat elevation axis height

Conclusions and Future Work

- Verification of single heliostat wind load coefficients of a 1:6 scale model in wind tunnel (WT) with field measurements
- Turbulence intensities and length scales of horizontal velocity (I_u, L_u^x) influence peak drag forces and azimuth moments, whereas vertical velocity component (I_u, L_u^x) influences peak lift forces and hinge moments
- Gaussian distribution is generally sufficient for frontal wind flow ($\beta \approx 0^\circ, 180^\circ$) and near-isotropic turbulence ($L_u^x/L_w^x = 2$) in wind tunnel but can underestimate peak loads in field measurements
- Scatter and inconsistency in lift forces and hinge moments from load cell data, whereas pressure data at ABLRF is more consistent with WT data
- There is a need to unify wind load coefficient derivations using load cells and pressure sensors with shape factors applied in design standards
